ABSTRACT

This study of the lichens of Hercules Glades Wilderness was designed 1) to collect lichens for a lichen flora census, 2) to collect lichens for elemental analysis, 3) to study the health and distributions of species most sensitive to air pollution, and 4) to assess the effects of air quality on lichens. Seventeen localities were studied throughout the wilderness. Samples of two species were collected at five localities for elemental analysis.

The lichen flora is quite diverse. There were 179 species present and several species very sensitive to sulfur dioxide. The distributions of these sensitive species do not show patterns that would suggest air quality problems. All of the lichens found were in good health and with normal fertility. The lichens studied by elemental analysis show normal levels of all elements with the possible exception of levels of manganese at Coy Bald. Therefore, there seem to be no indications of air quality problems in the wilderness.

Recommendations are for periodic (5 years) restudy of the lichens by elemental analysis. A complete lichen restudy of the lichen flora should be done every 10-15 years. If extensive manipulation of the vegetation of the balds is planned, a lichenologist should be consulted to prevent loss of species that grow only in the balds.
PREFACE

Under a contract with the U. S. Forest Service (USDA/42-649) a lichen study was to be performed in Hercules Glades Wilderness Area of the Mark Twain National Forest. This study was to survey the lichens of the wilderness, produce a census of the lichen flora, collect and analyze lichens for chemical contents and evaluate the lichen flora with reference to the air quality. This study was to establish baseline data for future restudy and determine the presence of any air quality problems that might be shown by the lichens at the time of the study. All work was done at the University of Minnesota with frequent consultation with Mr. Manfred Mielke, and with personnel on the Mark Twain National Forest.

The Forest Service personnel have been very helpful during the field work which has contributed significantly to the success of the project. The study was made possible by funds from the U. S. Forest Service, Mark Twain National Forest and NAS & PF Forest Health Protection. The assistance of all of these is gratefully acknowledged.
INTRODUCTION

Lichens are composite plants composed of two different types of organisms. The lichen plant body (thallus) is made of fungi and algae living together in a symbiotic arrangement in which both partners are benefited and the composite plant body can grow in places where neither component could live alone. The thallus has no protective layer on the outside, such as the epidermis of a leaf, so the air in the thallus has free exchange with the atmosphere. Lichens are slow growing (a few millimeters per year) and remain alive for many years and so must have a habitat that is relatively undisturbed in order to survive. Lichens vary greatly in their ecological requirements but almost all of them can grow in places that only receive periodic moisture. When moisture is lacking they go dormant until the next rain or dew-fall. Some species can grow in habitats with very infrequent occurrences of moisture while others need high humidity and frequent wetting in order to survive. This difference in moisture requirements is very important in the distribution of lichens.

Some species of lichens are known to be very sensitive to low levels of many atmospheric pollutants. Some are damaged or killed by levels of sulfur dioxide as low as 13 ug/cubic meter (annual average)(LeBlanc et al., 1972) or by nitrogen oxides at 3834-7668 ug/cubic meter or by other strongly oxidizing compounds such as ozone (Ross & Nash, 1983, Sigal & Nash, 1983). Other lichens are less sensitive and a few can tolerate levels of sulfur dioxide over 300 ug/cubic meter (Laundon, 1967, Trass, 1973). The algae of the thallus are the first to be damaged in areas with air pollution and the first indication of damage is discoloring and death of the algae, which quickly leads to the death of the lichen. After the lichen dies it disappears from the substrate within a few months to a year as it disintegrates and decomposes (Wetmore, 1982).

Lichens are more sensitive to air pollution when they are wet and physiologically active and are least sensitive when dry (Nash, 1973, Marsh & Nash, 1979) and are more sensitive when growing on acid substrates.

Contrary to some published reports (Medlin, 1985) there is little evidence that most lichens are good indicators of acid precipitation. However, Sigal & Johnston (1986) have reported that one
species of *Umbilicaria* shows visible damage due to artificial acid rain. They also report that similar symptoms were found in collections from various localities in North America. Lechowicz (1987) reported that acid rain only slightly reduced growth of *Cladina stellaris*, but Hutchinson et al. (1986) reported that extremely acid precipitation killed or damaged some mosses and lichens. Scott & Hutchinson (1987) showed temporary reduction of photosynthesis in *Cladina stellaris* and *C. rangiferina* after artificial acid rain.

Lichens are able to accumulate chemical elements in excess of their metabolic needs depending on the levels in the substrate and the air and, since lichens are slow growing and long lived, they serve as good summarizers of the environmental conditions in which they are growing. Chemical analysis of the thallus of lichens growing in areas of high fallout of certain elements will show elevated levels in the thallus. Toxic substances (such as sulfur) are also accumulated and determination of the levels of these toxic elements can provide indications of the sub-lethal but elevated levels in the air.

The Hercules Glades Wilderness is located in the Ozark Mountains in southwestern Missouri. The land is rolling hills with hardwood forests and openings. Oak (*Quercus*), hickory (*Carya*), and hackberry (*Celtis*) dominate the forested areas with some stands of maple (*Acer*) or shortleaf pines (*Pinus*). The rock openings have thin soil over limestone rocks with scattered juniper (*Juniperus*). Some of the openings have been burned to retard the encroachment of the forest.

There has been no systematic lichen collecting done in the wilderness area, but various collectors have collected some lichens in the Ozarks in the past and some of these may have been from within the wilderness. No references have been found to reports of lichens from Hercules Glades Wilderness.

**METHODS**

Field work was done during August and September, 1991. Collections in the wilderness were made at 17 localities and 968 lichen collections were obtained. A complete list of collection localities is given in Appendix I and are indicated on Fig. 1. Localities for collecting were selected first to give a general coverage of the wilderness, second, to sample all vegetational types, third, to be in
localities that should be rich in lichens. At each locality voucher specimens of all species found were collected to record the total flora for each locality and to avoid missing different species that might appear similar in the field. At some localities additional material of selected species was collected for chemical analysis (see below). While collecting at each locality observations were made about the general health of the lichens.

Identifications were carried out at the University of Minnesota with the aid of comparison material in the herbarium and using thin layer chromatography for identification of the special lichen products (lichen substances) where necessary. The original packet of each collection has been deposited in the University of Minnesota Herbarium and duplicates will be distributed to other herbaria. All specimens deposited at the University of Minnesota have been entered into the computerized data base maintained there.

**LICHEN FLORA**

The following list of lichens is based on my collections. There are no literature reports of lichens previously collected in the Hercules Glades Wilderness Area. Species found only once are indicated by "Rare". In the first columns the letters indicate the sensitivity to sulfur dioxide, if known, according to the categories proposed by Wetmore (1983): S=Sensitive, I=Intermediate, T=Tolerant. S-I is intermediate between Sensitive and Intermediate and I-T is intermediate between Intermediate and Tolerant. Species in the Sensitive category are absent when annual average levels of sulfur dioxide are above 50ug per cubic meter. The Intermediate category includes those species present between 50 and 100ug and those in the Tolerant category are present at over 100ug per cubic meter.

**SPECIES**

- *Acarospora fuscata* (Nyl.) Arn.
- *Anzia colpodes* (Ach.) Stizenb.
- *Arthonia patellulata* Nyl. :Rare
- *Arthonia pyrrhuliza* Nyl. :Rare
- 1 additional unidentified species of *Arthonia*
- *Arthrothelium ruanum* (Mass.) Zw.
1 additional unidentified species of *Arthothelium*

*Aspicilia caesiocinerea* (Nyl. ex Malbr.) Arn.: Rare

*Aspicilia cinerea* (L.) K"orb.: Rare

*Aspicilia contorta* (Hoffm.) Kremp.

* Bacidia* rubella* (Hoffm.) Mass.: Rare
  *Bacidia suffusa* (Fr.) Schneid.
  *Bacidia trachona* (Ach.) Lett.
  *Buellia novomexicana* B. de Lesd.
  *Buellia spuria* (Schaer.) Anzi
  *Buellia stigmaea* Tuck.: Rare

* Buellia* stilingiana* Steiner

1 additional unidentified species of *Buellia*

*Calicium abietinum* Pers.: Rare

*Calicium salicina* Pers.: Rare

*Caloplaca camptidia* (Tuck.) Zahlbr.

S-I *Caloplaca cerina* (Ehrh.) Th. Fr.

*Caloplaca chrysophthalma* Degel.

*Caloplaca cinnabarina* (Ach.) Zahlbr.

*Caloplaca citrina* (Hoffm.) Th. Fr.

S *Caloplaca flavorubescens* (Huds.) Laund.

*Caloplaca flavivirescens* (Wulf.) Dalla Torre & Sarnth.

*Caloplaca holocarpa* (Hoffm.) Wade

*Caloplaca pollinii* (Mass.) Jatta

*Caloplaca sarcopoides* (K"orb.) Zahlbr.

*Caloplaca squamosa* (B. de Lesd.) Zahlbr.: Rare

2 additional unidentified species of *Caloplaca*

S-I *Candelaria concolor* (Dicks.) B. Stein

*Candelaria fibrosa* (Fr.) M"ull. Arg.

*Candelariella efflorescens* R. Harris & Buck

S-I *Candelariella xanhostigma* (Ach.) Lett.

*Catapyrenium lachneum* (Ach.) R. Sant.

*Catapyrenium tuckermanii* (Rav. ex Mont.) Thoms.

*Catillaria nigroclavata* (Nyl.) Schuler: Rare

*Cetraria viridis* Schwein. in Halsey

*Chaenothecopsis debilis* (Turn. & Borr. ex Sm.) Tibell: Rare

*Chaenothecopsis rubescens* Vain.: Rare

*Chaenothecopsis sayonica* (R"as.) Tibell

*Chrysothrix candelaris* (L.) Laund.

*Cladina subtenuis* (des Abb.) Hale & W. Culb.

*Cladonia bacillaris* Nyl.

I *Cladonia cristatella* Tuck.

*Cladonia cryptochlorophaeas* Asah.

*Cladonia furcata* (Huds.) Schrad.: Rare

*Cladonia grayi* G. K. Merr. ex Sandst.

*Cladonia parasitica* (Hoffm.) Hoffm.

*Cladonia peziziformis* (With.) Laundon

*Cladonia piedmontensis* G. K. Merr.: Rare

*Cladonia polycarpoidea* Nyl. in Zawackh

*Cladonia pyxidata* (L.) Hoffm.

*Cladonia robbinsii* Evans

*Cladonia sobolescens* (Nyl.) Vain.: Rare

*Cladonia symphycarpa* (Ach.) Fr.

*Coccocarpia palmicola* (Spreng.) Arvid. & Galloway

*Collema conglomeratum* Hoffm.
Collema nigrescens (Huds.) DC.
Collema polycarpon Hoffm. :Rare
Collema subflaccidum Degel.
Collema texanum Tuck.
  1 additional unidentified species of Collema
Conotrema urceolatum (Ach.) Tuck.
Dermatocarpon miniatum (L.) Mann
Dimelaena oreina (Ach.) Norm. :Rare
Endocarpon pusillum Hedw.
Gonohymenia nigritella (Lett.) Henss.

I
Graphis scripta (L.) Ach.
Haematomma elatinum (Ach.) Mass. :Rare
Haematomma pustulatum Brodo & W. Culb.
Heppia lutosa (Ach.) Nyl. :Rare
Heterodermia echinata (Tayl.) W. Culb.
Heterodermia granulifera (Ach.) W. Culb.
Heterodermia hypoleuca (Muhl.) Trev.
Heterodermia obscurata (Nyl.) Trev.
Heterodermia speciosa (Wulf.) Trev.

I
Hyperphyscia adglutinata (Fl"orke) Mayrh. & Poelt
Hyperphyscia syncolla (Tuck. ex Nyl.) Kalb
Lecanora caesiorubella Ach.
Lecanora hybocarpa (Tuck.) Brodo
Lecanora minutella Nyl. :Rare

T
Lecanora muralis (Schreb.) Rabenh.
Lecanora strobilina (Spreng.) Kieff.
Lecanora subimmergens Vain.
Lecanora valesiaca (M"ull. Arg.) Stizenb.
  1 additional unidentified species of Lecanora
Lecidea berengeriana (Mass.) Nyl.
Lecidea erratica K"orb. :Rare
  3 additional unidentified species of Lecidea
Lecidella euphorea (Fl"orke) Hert.
Lepraria finkii (B. de Lesd. in Hue) R. Harris
Leptogium burnetiae Dodge
Leptogium byssinum (Hoffm.) Zw. ex Nyl. :Rare
Leptogium chloromelum (Sw. ex Ach.) Nyl. :Rare
Leptogium cyanescens (Rabenh.) K"orb.
Leptogium lichenoides (L.) Zahlbr.
Leptogium milligranum Sierk
Leptogium teretiusculum (Wallr.) Am. :Rare
Maronea constans (Nyl.) Hepp
Megaspora verrucosa (Ach.) Hafeln. & Wirth
Micarea globulosella (Nyl.) Coppins :Rare
Micarea misella (Nyl.) Hedl.
  1 additional unidentified species of Micarea
Mycocalicium subtile (Pers.) Szat. :Rare
Ochrolechia arborea (Kreyer) Almb.
Ochrolechia verrucosa Kalb.

I
Opegrapha varia Pers.
Pannaria lurida (Mont.) Nyl.
Parmelia angustiphylla (Gyeln.) ined.
Parmelia aurulenta Tuck.
Parmelia boliana M"ull. Arg.

Pyxine caesiopruinosa (Nyl.) Imsh.
Pyxine sorediata (Ach.) Mont.
DISCUSSION OF FLORA

This list of 179 species presents the first listing of lichens for the wilderness and includes some species rare in eastern North America, such as *Caloplaca sarcopsisoides*, *C. camptidia*, and *Anzia colpodes*. There are still 17 unidentified species and some of these may be undescribed.

Some of the species, such as *Buellia novomexicana* and *Collema texanum*, were previously only known from western North America. The most common species are *Cladina subtenuis*, *Collema conglomeratum*, *Leptogium milligranum*, *Parmelia reticulata*, *P. subtinctoria*, and *Physconia detersa*.

There were no cases where lichens sensitive to sulfur dioxide were observed to be damaged or killed. All species normally found fertile were also fertile in the wilderness. The numerous "Rare" species seem to be rare because of special ecological requirements or they are rare throughout their distributional range in North America and are not rare because of air pollution. These observations indicate that there is no air quality degradation in the area due to sulfur dioxide that causes observable damage to the lichen flora.

Another way of analyzing the lichen flora of an area is to study the distributions of the sensitive species within the area to look for voids in the distributions that might be caused by air pollution. Showman (1975) has described and used this technique in assessing sulfur dioxide levels around a power plant in Ohio. Only the very common species have meaning with such a technique.
since the rare species may be absent due to other factors.

There are only a few lichens in the wilderness with known sensitivity to sulfur dioxide according to the list presented in Wetmore (1983) and many of these are not very common. Species in the most sensitive category are usually absent when sulfur dioxide levels are above 50ug per cubic meter average annual concentrations. The S-I category is between Sensitive and Intermediate. The species that occur in the wilderness in these two most sensitive categories are as follows with the sensitivity category indicated in the first column.

- S-I Caloplaca cerina (Ehrh.) Th. Fr.
- S Caloplaca flavorubescens (Huds.) Laund.
- S I Candelaria concolor (Dicks.) B. Stein
- S I Candelariella xanthostigma (Ach.) Lett.
- S Parmelia reticulata Tayl.
- S Ramalina americana Hale
- S I Xanthoria fallax (Hepp in Arn.) Arn.

The distributions of these species are mapped (Fig. 2-8). Although these species are not found at all localities and some are rare, there is no indication that the voids in the distributions are due to poor air quality. Some of the localities where collections were made do not have suitable habitats for some of these species.

ELEMENTAL ANALYSIS

An important method of assessing the effects of air quality is by examining the elemental content of the lichens (Nieboer et al, 1972, 1977, 1978; Erdman & Gough, 1977; Puckett & Finegan, 1980; Nash & Sommerfeld, 1981). Elevated but sublethal levels of sulfur or other elements might indicate incipient damaging conditions.

METHODS

Lichen samples of two species were collected in spunbound olefin bags at various localities in different parts of the wilderness for laboratory analysis. At some localities both species were not present in quantities needed for the analysis. Species collected and the substrates were Cladina subtenuis on soil and rocks, and Parmelia rudecta on trees. These species were selected because they are the only ones present in abundance and relatively easy to clean.
Five localities were selected for elemental analysis and are indicated on the map of collection localities. These localities are: 2 miles northwest of Hercules Lookout Tower, 0.5 miles north of Persimmon Hollow, along trail south of Long Creek (no other lichens collected here, indicated by square on map), 0.5 miles northwest of Hercules Lookout Tower, and 0.5 miles northeast of Coy Bald. Ten to 20 grams of each species were collected at each locality.

Lichens were air dried and cleaned of all bark and detritis under a dissecting microscope, but thalli were not washed. Three samples of each collection were submitted for analysis. Analysis was done for sulfur and multi-element analysis by the Research Analytical Laboratory at the University of Minnesota. In the sulfur analysis, a ground and pelleted 100-150 mg sample was prepared for total sulfur by dry combustion and measurement of evolved sulfur dioxide on a LECO Sulfur Determinator, model no. SC-132, by infra red absorption. Multi-element determination for Ca, Mg, Na, K, P, Fe, Mn, Al, Cu, Zn, Cd, Cr, Ni, Pb, and B were determined simultaneously by Inductively Coupled Plasma (ICP) Atomic Emission Spectrometry. For the ICP, one gram of dried plant material was dry ashed in a 20 ml high form silica crucible at 485 degrees Celsius for 10-12 hrs. Crucibles were covered during the ashing as a precaution against contamination. The dry ash was boiled in 2N HCl to improve the recovery of Fe, Al and Cr and followed by transfer of the supernatant to 7 ml plastic disposable tubes for direct determination by ICP.

RESULTS AND DISCUSSION

Table 1 gives the results of the analyses for all replicates arranged by species. Table 2 gives the means and standard deviations for each set of replicates. Some of the reported values were at or below the lower detection limits of the instruments. If one value of the set of 3 replicates was at or below the detection limit, 0.7 of the detection limit was used in the calculations and the value is listed with "**" in the tables. If two or more values were at or below the detection limit, no calculations were done and these are indicated with "#" in the tables.

All of the levels found in the Hercules Glades Wilderness lichens are within typical limits for similar lichens in clean areas. The levels in *Parmelia rudecta* are similar to those reported from Minnesota and Wisconsin by Wetmore (1991). The slightly higher level of manganese at Coy Bald in

both species is an exception. According to Mr. Jerry Gott of the Mark Twain National Forest, some of the balds have high concentrations of manganese in the soils, and some even have iron-manganese concretions on the soil surface or manganese stains on the rocks. The higher levels of manganese in the lichens at Coy Bald may reflect the soil conditions.

The sulfur levels in lichens tested range from 470 to 1220 ppm for all samples and these values are near background levels as cited by Solberg (1967) Erdman & Gough (1977), Nieboer et al (1977) and Puckett & Finegan (1980) for other species of lichens. Levels may be as low as 200-300 in the arctic (Tomassini et al, 1976) while levels in polluted areas are 4300-5200 ppm (Seaward, 1973) or higher. Different species may accumulate different amounts of elements and this is evident when comparing sulfur levels of the two species. Cladina subtenuis has lower levels than Parmelia rudecta. Even when taking these differences into account there is no clear trend in accumulated levels of sulfur.

CONCLUSIONS

There is no indication that the lichens of the Hercules Glades Wilderness are being damaged by air quality. The lichen flora is reasonably diverse for such an area and there is no impoverishment of the lichen flora in any part of the Hercules Glades. There are only a few species with known sensitivities to sulfur dioxide in the wilderness and some of those that are most sensitive are quite rare. This rarity seems to be due more to ecological and climatic conditions than pollution since these species are quite healthy when present. The maps of the distributions of the more sensitive species do not show any significant voids that are not due to normal ecological conditions. There is no evidence of damaged or dead lichens in any area where healthy ones are not also present. The elemental analyses do not show abnormal accumulations of polluting elements at any locality, with the exception of manganese at Coy Bald.

RECOMMENDATIONS

Although there seem to be no air quality problems in the Hercules Glades Wilderness now, periodic restudy is recommended. Elemental analysis should be done every 5 years and a complete floristic restudy done every 10-15 years.
If plans are developed to do extensive manipulations of the vegetation in the bal ds to control tree encroachment, a lichenologist should be consulted to help design the work so that lichens that grow only in the bal ds are not lost from the lichen flora.

APPENDIX I

Collection Localities

Collection numbers are those of Clifford Wetmore. All collections are listed in ascending order by collection number and date of collection.

Taney County, Missouri

68518 north of Persimmon Hollow. On saddle ridge west of trail with open areas, hickory, oaks and juniper. Sec. 20, T23n, R18W. 30 Aug. 1991. CHEM.

68910 western side of wilderness.

68911- Hercules Glades, Mark Twain Nat. For. Along trail 68972 0.5 miles southwest of Upper Pilot Knob. On ridge near small pond with oak, hickory, juniper and maple. Sec. 9, T23N, R18W. 5 Sept. 1991.

69031- Hercules Glades, Mark Twain Nat. For. One mile 69103 southeast of Coy Bald. On west facing hillside around openings with juniper and oaks and some hickory. Sec. 6, T23N, R18W. 6 Sept. 1991.

Hercules Glades, Mark Twain Nat. For. Along trail south of Long Creek (= loc. of 1 Sept. but 0.5 miles SE). On ridge and northwest slope in openings, junipers and oaks. Sec. 14, T23N, R18W. 7 Sept. 1991. CHEM.

69104- Hercules Glades, Mark Twain Nat. For. 0.5 miles 69166 northwest of Hercules Lookout Tower. On ridge and northeast slope with hickory, oaks and juniper. Sec. 12, T23N, R18W. 7 Sept. 1991. CHEM.

69167- Hercules Glades, Mark Twain Nat. For. 0.5 miles 69225 northeast of Coy Bald. On plateau near small rock piles among oaks, hickory and juniper with small openings. Sec. 9, T23N, R18W. 8 Sept. 1991. CHEM.
APPENDIX II

Species Sensitive to Sulfur Dioxide

Based on the list of lichens with known sulfur dioxide sensitivity compiled from the literature, the following species in Hercules Glades Wilderness fall within the Sensitive and Sensitive/Intermediate categories as listed by Wetmore, 1983. Sensitive species (S) are those present only under 50ug sulfur dioxide per cubic meter (average annual). The intermediate category includes species present between 50ug and 100ug. The SI group falls between the Sensitive and Intermediate categories. Open circles are localities where the species was not found and solid circles are where it was found.

Note: Refer to text for interpretation of these maps and precautions concerning absence in parts of the park.
